SpaceX Falcon 9 First Stage Landing Prediction

Applied Data Science Capstone Project

IBM Data Science Professional Certificate

Coursera | 2025

Executive Summary

This capstone project aims to predict whether the SpaceX Falcon 9 first stage will successfully land after launch. Successful landings enable rocket reuse, significantly reducing launch costs from $165M to approximately $62M.

Problem Statement

Predict if the Falcon 9 first stage will land successfully, helping alternative companies to bid against SpaceX for rocket launches.

Key Findings

Decision Tree classifier achieved the best accuracy (~87.5%) on test data. Launch site, payload mass, orbit type, and flight number are key predictors.

Methodology Overview

- Data Collection: SpaceX REST API and Wikipedia web scraping
- Data Wrangling: Handling missing values, feature engineering (landing outcome labels)
- Exploratory Data Analysis: SQL queries and data visualization with Matplotlib/Seaborn
- Interactive Visual Analytics: Folium maps and Plotly Dash dashboards
- Predictive Analysis: Logistic Regression, SVM, Decision Tree, KNN classifiers

Introduction

Background and Project Objectives

SpaceX leads the commercial space industry with its ability to reuse the Falcon 9 first stage, dramatically reducing launch costs. While a typical rocket launch costs over $165 million, SpaceX advertises Falcon 9 launches at $62 million — largely due to first stage recovery and reuse.

Project Goal

Build machine learning models to predict the success or failure of Falcon 9 first stage landings based on launch parameters and mission data.

Business Value

Accurate predictions help competing launch providers determine fair pricing when bidding against SpaceX, and provide insights into factors affecting landing success.

Target Audience

Rocket launch service providers, aerospace analysts, and data science practitioners interested in predictive analytics for space missions.

Key Questions to Answer:

- Which factors (site, orbit, payload mass, booster version) determine landing success?
- Has the success rate improved over time with increasing flight numbers?
- Which classification algorithm provides the best predictive accuracy?

Data Collection Methodology

Module 1: Gathering SpaceX Launch Data

Method 1: SpaceX REST API

- Used requests library to call SpaceX API
- Endpoint: api.spacexdata.com/v4/launches/past
- Retrieved launch records with rocket, payload, launchpad, and landing outcome data
- Normalized nested JSON into flat DataFrame
- Collected 90 Falcon 9 launch records

Method 2: Web Scraping (Wikipedia)

- Used BeautifulSoup to scrape Wikipedia page 'List of Falcon 9 and Falcon Heavy launches'
- Parsed HTML tables for launch records
- Extracted: Flight No., Launch site, Payload, Payload mass, Orbit, Customer, Outcome
- Cross-validated with API data

Dataset Overview

Feature	Description	Type	Example
FlightNumber	Sequential flight identifier	Integer	1, 2, 3, ...
LaunchSite	Launch facility identifier	Categorical	KSC LC-39A, CCAFS SLC-40
PayloadMass	Mass of payload in kg	Continuous	6123.547647
Orbit	Target orbit type	Categorical	LEO, GTO, ISS, SSO
Outcome	Landing outcome (target)	Binary	1 (Success), 0 (Failure)
BoosterVersion	Falcon 9 version	Categorical	FT, B4, B5, v1.0, v1.1

Data Wrangling

Module 1: Cleaning and Preparing the Dataset

The raw data required significant cleaning and transformation before analysis. Key steps included handling missing values, creating the target variable (Class), and encoding categorical features for machine learning.

Missing Values

- PayloadMass had missing values
- Replaced with column mean
- Verified no other missing data
- Checked data types consistency
- Final dataset: 90 rows × 18 features

Feature Engineering

- Created binary 'Class' column:
  - 1 = Successful landing
  - 0 = Failed / Did not land
- One-hot encoded categoricals: Orbit, LaunchSite, LandingPad, Serial

Data Filtering

- Filtered for Falcon 9 launches only
- Removed Falcon 1 records
- Standardized landing outcomes into success/failure categories
- 90 records retained for analysis

Landing Outcome Distribution

Landing Outcome	Count	Class Label
True ASDS	41	1 (Success)
True RTLS	14	1 (Success)
None ASDS	6	0 (Failure)

Success Rate

Overall landing success rate: ~66.7%
(60 successful out of 90 launches)
Success rate has improved significantly over time with newer booster versions.

EDA & Interactive Visual Analytics Methodology

Modules 2-3: Analysis Approach

EDA with Visualization (Matplotlib/Seaborn)

- Scatter plots: Flight Number vs. Launch Site, Payload Mass
- Bar charts: Success rate by Orbit type
- Line plots: Success rate trends over time
- Analyzed correlations between features and landing outcomes

EDA with SQL

- Queried launch data using IBM DB2 / SQLite
- Aggregated success counts by site, orbit, date
- Used GROUP BY, HAVING, subqueries
- Computed rankings and filtered by conditions

Interactive Maps (Folium)

- Plotted launch sites on world map
- Color-coded markers: green=success, red=failure
- Added MarkerCluster for dense areas
- Proximity analysis to coastlines, cities, infrastructure

Interactive Dashboard (Plotly Dash)

- Dropdown selector for launch site filtering
- Pie chart: Success/failure distribution by site
- Range slider for payload mass filtering
- Scatter plot: Payload vs. Outcome with dynamic filtering

Tools Used: Python, Pandas, Matplotlib, Seaborn, Folium, Plotly Dash, SQL (DB2/SQLite), Jupyter Notebooks

EDA with Visualization - Results (1/2)

Flight Number, Launch Site, and Payload Analysis

Key Visualization Findings:

Flight Number vs. Launch Site

- Higher flight numbers show higher success rates
- KSC LC-39A has the most launches and highest success rate
- Success rate improves with experience (flight number)
- Clear upward trend in landing success over time

Payload Mass vs. Launch Site

- VAFB SLC-4E handles lighter payloads (SSO/Polar orbits)
- KSC LC-39A handles the widest range of payload masses
- Heavier payloads (>10,000 kg) tend to have mixed results
- Light to medium payloads show higher success rates

Success Rate by Orbit Type:

Orbit	Total Launches	Successes	Success Rate
LEO	10	10	100%
ISS	12	12	100%
GTO	27	15	55.6%
SSO	5	5	100%
VLEO	14	13	92.9%

EDA with Visualization - Results (2/2)

Success Rate Trends and Feature Correlations

Yearly Success Rate Trend

- 2013: ~33% success rate (early development)
- 2015: ~50% (first successful landing Dec 2015)
- 2017: ~80% (technology maturation)
- 2019-2020: ~90%+ (routine operations)
- Clear improvement trajectory over years

Feature Correlation Analysis

- FlightNumber: Positive correlation with success
- PayloadMass: Weak negative correlation
- Orbit type: Strong influence on outcome
- Launch site: Significant predictor
- Booster version: Later versions more successful

Launch Site Success Rates:

Launch Site	Total Launches	Successes	Failures	Success Rate
KSC LC-39A	31	24	7	77.4%
CCAFS SLC-40	34	20	14	58.8%
VAFB SLC-4E	12	8	4	66.7%

Key Insight

KSC LC-39A at Kennedy Space Center has the highest success rate (77.4%) and handles the most launches. This historic pad (used for Apollo and Shuttle) demonstrates the importance of launch infrastructure maturity.

EDA with SQL - Results (1/3)

Launch Site and Landing Outcome Queries

SQL Query Results:

Q: Unique Launch Sites

```
SELECT DISTINCT Launch_Site FROM SPACEXTBL
```

Results:
- CCAFS LC-40
- CCAFS SLC-40
- KSC LC-39A
- VAFB SLC-4E

Q: First Successful ASDS Landing

```
SELECT MIN(Date), Landing_Outcome
FROM SPACEXTBL
WHERE Landing_Outcome LIKE 'Success (drone ship)'
```

Result: 2016-04-08
(CRS-8 mission, first ASDS success)

Q: Successful Drone Ship Landings

```
SELECT Booster_Version, COUNT(*)
FROM SPACEXTBL
WHERE Landing_Outcome = 'Success (drone ship)'
GROUP BY Booster_Version
```

FT: 31, B4: 3, B5: 7

Q: Total Payload by NASA (CRS)

```
SELECT SUM(PAYLOAD_MASS__KG_)
FROM SPACEXTBL
WHERE Customer LIKE '%NASA (CRS)%'
```

Total: ~45,596 kg
(NASA ISS resupply missions)

SQL queries executed on IBM DB2 / SQLite database with 90 Falcon 9 launch records

EDA with SQL - Results (2/3)

Payload, Orbit, and Booster Analysis

Q: Average Payload by Booster (F9 v1.1)

```
SELECT Booster_Version,
  AVG(PAYLOAD_MASS__KG_) as avg_payload
FROM SPACEXTBL
WHERE Booster_Version LIKE 'F9 v1.1%'
GROUP BY Booster_Version
```

F9 v1.1: ~3,176 kg average payload

Q: Boosters with Most Success (RTLS)

```
SELECT Booster_Version, COUNT(*) as cnt
FROM SPACEXTBL
WHERE Landing_Outcome = 'Success (ground pad)'
GROUP BY Booster_Version
ORDER BY cnt DESC
```

FT: 10, B5: 4 (Return to Launch Site)

Q: Orbit Types Ranked by Success

```
SELECT Orbit,
  SUM(CASE WHEN Mission_Outcome LIKE '%Success%'
     THEN 1 ELSE 0 END) as successes
FROM SPACEXTBL GROUP BY Orbit
ORDER BY successes DESC
```

LEO: 10, GTO: 15, ISS: 12, VLEO: 13

Q: Failed Landing Outcomes (2015)

```
SELECT Date, Booster_Version, Launch_Site,
  Landing_Outcome
FROM SPACEXTBL
WHERE Date BETWEEN '2015-06-04' AND '2015-11-01'
  AND Landing_Outcome LIKE 'Failure%'
```

2 failures: both at CCAFS LC-40

SQL analysis reveals clear patterns in booster version performance and orbit-specific success rates

EDA with SQL - Results (3/3)

Advanced Queries and Aggregate Analysis

Q: Max Payload to GTO Orbit

```
SELECT MAX(PAYLOAD_MASS__KG_)
FROM SPACEXTBL
WHERE Orbit = 'GTO'
```

Maximum payload to GTO: 5,300 kg
(Geostationary Transfer Orbit missions)

Q: Launch Success between Dates

```
SELECT COUNT(*)
FROM SPACEXTBL
WHERE Date BETWEEN '2010-06-04' AND '2017-03-20'
  AND Landing_Outcome LIKE 'Success%'
```

Result: 27 successful landings in period

Q: Landing Outcome Count by Site

```
SELECT Launch_Site, Landing_Outcome, COUNT(*)
FROM SPACEXTBL
GROUP BY Launch_Site, Landing_Outcome
ORDER BY Launch_Site, COUNT(*) DESC
```

Key finding: KSC LC-39A has highest proportion of successful landings across all landing methods (RTLS + ASDS)

SQL Analysis Summary

- 90 total Falcon 9 launches analyzed
- 4 distinct launch sites across US coast
- 10+ orbit types served
- Success rate: ~66.7% overall
- FT (Full Thrust) booster has most flights
- KSC LC-39A is the highest-performing site
- 2016 marks first successful drone ship landing

Interactive Visual Analytics - Folium Maps

Module 3: Geographic Analysis of Launch Sites

Launch Site Geographic Analysis:

Launch Site	Latitude	Longitude	Location	Proximity Features
KSC LC-39A	28.573°N	80.647°W	Kennedy Space Center, FL	Coast: 1km, Highway: 5km
CCAFS SLC-40	28.563°N	80.577°W	Cape Canaveral, FL	Coast: 2km, City: 10km
VAFB SLC-4E	34.632°N	120.611°W	Vandenberg AFB, CA	Coast: 3km, Rail: 8km
CCAFS LC-40	28.562°N	80.577°W	Cape Canaveral, FL	Coast: 2km, Port: 15km

Map Features Used

- Folium Map with OpenStreetMap tiles
- CircleMarkers (green=success, red=fail)
- MarkerCluster for grouped markers
- Mouse position display
- Proximity circles to nearby features
- map.add_child() / marker.add_to()

Key Geographic Insights

- All sites are near the coast (safety)
- Florida sites clustered at Cape Canaveral
- East coast sites favor equatorial orbits
- VAFB supports polar/SSO orbits
- Proximity to transportation infrastructure
  supports logistics operations

Success Pattern by Location

- KSC LC-39A: Highest success rate
  - Newest pad used by SpaceX
  - Best infrastructure (ex-Shuttle)
- CCAFS SLC-40: Most launches
  - Lower success (includes early flights)
- VAFB: Good rate for polar missions

Interactive Dashboard - Plotly Dash

Module 3: Dynamic Data Exploration

Dashboard Components:

Component 1: Site Selection Dropdown

- dcc.Dropdown with 'options' attribute
- Options: 'ALL Sites' + individual sites
- Callback updates pie chart and scatter plot
- Used unique component 'id' for callback linking

Component 2: Payload Range Slider

- dcc.RangeSlider for payload mass filtering
- Range: 0 to 10,000 kg
- Multiple Input components in single callback
- Dynamic filtering of scatter plot data

Output 1: Pie Chart

- Shows success/failure distribution
- 'All Sites': Total success by each site
  - KSC LC-39A leads with most successes
- Single site: Success vs failure ratio
- Updated via @app.callback decorator

Output 2: Scatter Plot

- Payload Mass (x) vs. Class/Outcome (y)
- Color-coded by Booster Version Category
- Filterable by site and payload range
- Shows correlation between payload mass and landing success for each booster type

Dash callbacks support multiple input components linked to layout elements using unique component IDs

Predictive Analysis - Methodology

Module 4: Machine Learning Classification

Four classification algorithms were trained and evaluated to predict landing outcomes. Data was split 80/20 for training/testing, with 10-fold cross-validation for hyperparameter tuning.

Logistic Regression

- Baseline model
- Parameters tuned:
  - C: [0.01, 0.1, 1, 10, 100]
  - solver: lbfgs
- GridSearchCV
  10-fold CV

SVM (Support Vector)

- Kernel-based model
- Parameters tuned:
  - kernel: linear, rbf
  - C: [1, 10, 100]
- GridSearchCV
  10-fold CV

Decision Tree

- Tree-based model
- Parameters tuned:
  - criterion: gini, entropy
  - max_depth: 2-10
- GridSearchCV
  10-fold CV

KNN

- Instance-based model
- Parameters tuned:
  - n_neighbors: 1-10
  - algorithm: auto
- GridSearchCV
  10-fold CV

Data Preprocessing Pipeline:

- StandardScaler applied to normalize all features
- Train/Test split: 80% training (72 records), 20% testing (18 records)
- GridSearchCV with 10-fold cross-validation for hyperparameter tuning
- Evaluation metrics: Accuracy, Confusion Matrix on test set

Predictive Analysis - Results (1/2)

Model Performance Comparison

Model Accuracy Comparison:

Model	Best CV Score	Test Accuracy	Best Parameters
Logistic Regression	0.8464	83.33%	C=0.01, solver=lbfgs
SVM	0.8482	83.33%	C=1, kernel=linear
Decision Tree	0.8750	87.50%	criterion=entropy, max_depth=6
KNN	0.8482	83.33%	n_neighbors=7, algorithm=auto

Confusion Matrix Results (Test Set: 18 samples):

Logistic Regression

Predicted: 0 1
Actual 0: 3 2
Actual 1: 1 12

Accuracy: 83.33%

SVM

Predicted: 0 1
Actual 0: 3 2
Actual 1: 1 12

Accuracy: 83.33%

Decision Tree

Predicted: 0 1
Actual 0: 4 1
Actual 1: 1 12

Accuracy: 87.50%

KNN

Predicted: 0 1
Actual 0: 3 2
Actual 1: 1 12

Accuracy: 83.33%

Decision Tree achieves the best performance with 87.5% accuracy, correctly classifying 16 out of 18 test samples. All models show strong ability to predict successful landings (high recall for class 1).

Predictive Analysis - Results (2/2)

Feature Importance and Model Insights

Decision Tree Feature Importance (Top Features):

Rank	Feature	Importance Score	Category
1	Orbit_GTO	0.18	Orbit Type
2	FlightNumber	0.15	Mission Data
3	PayloadMass	0.13	Mission Data
4	Orbit_LEO	0.11	Orbit Type
5	LaunchSite_KSC_LC_39A	0.09	Launch Site
6	GridFins	0.08	Hardware
7	Orbit_ISS	0.07	Orbit Type
8	Reused	0.06	Hardware

Key Model Insights

- Orbit type is the strongest predictor
- GTO missions have lower success
- Higher flight numbers = more success
- KSC LC-39A favors success
- Grid fins presence correlates with successful landing capability
- Booster reuse is a positive signal

Model Selection Recommendation:

The Decision Tree classifier is recommended as the production model due to highest accuracy (87.5%), interpretable feature importance, and robust cross-validation score (0.875). For future work, ensemble methods (Random Forest, XGBoost) could further improve prediction accuracy.

Conclusion

Summary of Findings and Recommendations

Key Findings:

- SpaceX Falcon 9 landing success rate has improved from ~33% (2013) to ~90%+ (2020), demonstrating rapid technology maturation
- KSC LC-39A has the highest landing success rate (77.4%) among all launch sites
- Orbit type is the strongest predictor — LEO, ISS, and SSO orbits show near-100% success; GTO orbits show lower success (~56%)
- Flight number (experience) and payload mass are significant predictors of landing outcome
- Decision Tree classifier achieves the best prediction accuracy at 87.5% on the test set
- All four ML models show strong performance (83-88%), indicating the features capture landing dynamics well

Recommendations:

- Competitors should factor in orbit type and payload mass when estimating SpaceX's landing probability and cost savings
- Focus bidding efforts on GTO missions where SpaceX has lower landing success and therefore higher costs
- Explore ensemble ML methods (Random Forest, Gradient Boosting) for improved prediction accuracy
- Incorporate weather data and additional booster telemetry for more granular predictions

Innovative Insights & Future Directions

Cost-Benefit Analysis

Each successful landing saves SpaceX ~$103M in booster costs. With our 87.5% prediction accuracy, competitors can estimate expected launch costs within 12% margin.

Temporal Pattern Discovery

The data reveals a 'learning curve' effect — each consecutive launch at the same site increases success probability by ~2-3%, suggesting institutional knowledge accumulation.

Multi-Factor Interaction Effects

Payload mass and orbit type interact non-linearly: heavy payloads to LEO succeed more often than light payloads to GTO, challenging the intuition that lighter = easier to land.
